Abstrak

Objective : Diabetes Mellitus has been known as a causal factor for sexual dysfunction in men due to neuropathic diabetic, vascular insufficiency and psychological problems. Female sexual dysfunction in diabetic patients has not been studied yet, because of limited scientific experiments in this subject. The purpose of this study is to get the prevalence of female sexual dysfunction in diabetic patients at Hasan Sadikin Hospital Bandung.

Method : This study was done to 100 women with diabetes mellitus who visited Endocrinology Out Patient Clinic at Hasan Sadikin Hospital Bandung. The study was performed using The Index of Female Sexual Function (IFSF) questionnaires with interview technic. Control population was 110 women who visited or worked at Hasan Sadikin Hospital Bandung. The responses of the questionnaires were analyzed to determine whether subject of this study experience sexual dysfunction or not.

Result : Women with diabetes mellitus were more likely to suffer from sexual dysfunction than population control (36 % vs 26 % ; $p < 0.05$). Women with diabetes mellitus complained more about decreased lubrication of vagina than population control (32 % vs 15 % ; $p = 0.008$). Age and length of suffering from diabetes mellitus are statistically not significant for causing female sexual dysfunction.

Conclusion : Sexual problems are more likely to occur in women with diabetes mellitus.
