### Abstrak

The aim of this study is to obtain information about the mouse tongue muscle rendered using micro-computed tomography ( $\mu$ CT) at low, middle, and high magnifications. Three-dimensional (3D)  $\mu$ CT is used in various fields. Most  $\mu$ CT observations are restricted to hard tissue in biomaterial samples. Recently, with the use of osmium tetroxide,  $\mu$ CT has been effectively employed to observe soft tissue; it is now believed that  $\mu$ CT observation of soft tissue is feasible. On the other hand, the structure of the tongue muscle has been well studied, but cross-sectional imaging enhanced by 3D rendering is lacking. We chose the mouse tongue as a soft tissue case study for  $\mu$ CT and generated cross-sectional images of the tongue enhanced by 3-D image rendering with histological resolution. During this observation, we developed new methods of low-magnification observation to show the relation between the tongue muscles and surrounding tissues. We also applied high-resolution  $\mu$ CT in high-magnification observation of muscle fiber fascicles. Our methodological techniques give the following results: (1) For low-magnification observation (field of view: 12,000  $\mu$ m), pretreatment with decalcification and freeze drying is suitable for observing the area between the muscle of the tongue and the bone around the tongue using  $\mu$ CT. (2) For middle-magnification observation (Field of view: 3,500  $\mu$ m), the use of osmium tetroxide to observe the muscle arrangement of the tongue by  $\mu$ CT is suitable. (3) For high-magnification observation (Field of view: 450  $\mu$ m), high-resolution  $\mu$ CT is suitable for observation of the transversus muscle fiber fascicles.
