### Abstrak

China has reduced the SO<sub>2</sub> emissions by 143% in the Five-Year Plan (2006-2010). However, air pollution is still a severe problem in some industrial regions in China, due to excessive use of coal and other fossil fuels. China plans to reduce SO<sub>2</sub> emissions by 8% in the new 12 Five-Year Plan (2011-2015), along with other CO<sub>2</sub> reduction targets and pollutants reduction targets. This study makes a comprehensive assessment of energy related SO<sub>2</sub> emissions control in China's 12th Five-Year Plan, by using a large scale non-linear integrated assessment model. According to the results, the popularization of wet type SO<sub>2</sub> scrubbers and improvement of the environmental emission standards play an important role in the achievement of SO<sub>2</sub> control target by 2015. In addition, the changes in energy consumption structure contribute to SO<sub>2</sub>; and other energy related emission controls, as well as the sustainable development of energy. In China, future environmental policy should concentrate on the provinces which emit SO<sub>2</sub> seriously, like Shandong, Inner Mongolia and Henan, or relevant industrial sectors such as electric & heat power, ferrous metals and nonmetal mineral sectors.
