Information on reliable factors to predict patient outcome is important for deciding upon the best treatment to increase loco-regional control, overall survival and quality of life of patients with head and neck squamous cell carcinoma (HNSCC). The objective of this study was to investigate the role of clinico-pathological parameters as predictors of disease recurrence in patients with HNSCC. We studied fifty patients who were seeking treatment for primary HNSCC in Westmead Hospital between 2002-2004. Univariate analysis was used to identify any significant association between clinico-pathological parameters and disease recurrence. It was showed that age ($p=0.008$), cTNM stage ($p=0.02$), size of tumour ($p=0.009$) and positive tumour margin ($p=0.002$) predicted the risk of the development of disease recurrence. In agreement with other studies we found that some traditional factors influenced disease recurrence. A longer follow-up study should be performed to assess the significance of these factors on overall survival as well as separate studies on prognostic indicators for patients with histologically negative lymph node.
