Abstrak

Phleomorphic adenoma is the most commonly found tumor of the salivary glands. This tumor is usually found in the postero-lateral region of the hard palate. In this case, a phleomorphic adenoma tumor situated in the oropharynx region was reported. The CT-Scan results showed an expansive and infiltrative appearance, suspected to be a malignancy, where wide excision was previously planned to be carried out. During surgery, the mass was found pedunculated in the soft palate. It was then decided to perform an excision as the choice of therapy.
