Abstrak

Garre's osteomyelitis is a type of Osteomyelitis which occur frequently in clinic. This disease can occur at any age, but mosk happen in and young adult, and frequently in mandible. Usually patient complaint about pains/hurt and jaw getting bigger and hard on bone jaw surface. Osteomyelitis is more frequently happen at incisive which expand medial and lateral. If the perios tissue inflamed, it tend to built a new bonetissue inside, which only can be seen by Rontgen photo if the cause is apikal infection. The infection tissue at the apical of teeth expand through bone surface and reach periosteum which can change periosteum from bone surface.

If the expand of the new bone apically, so it will be seen with periapical projection. And if the expand goes laterally, it will be seen with oclusal projection.

It will be discuss about the connection of Garre's Osteomyelitis Roentgen view in various type of projection and its diferential diagnosa in Roentgen will ostegenik sarkoma and about the other lesion which shown almost the same with it.
