### Abstrak

Two studies focused on perceived ingroup and outgroup variability in children as a function of status. In the first study, 7- and 9-year-old White and Black children distributed White and Black faces along the levels of several dimensions. White children perceived more ingroup than outgroup variability, whereas Black children perceived more outgroup than ingroup variability. In addition, White children favored their ingroup, whereas Black children did not. In a second study, 7- and 9-year-old boys and girls distributed ingroup and outgroup faces along the levels of several dimensions. As expected, boys displayed outgroup homogeneity and girls did not. The consequences of these findings are discussed.
