ABSTRACT

Fishing activities currently require good management, in order to meet the protein needs of the community. Knowledge on the distribution pattern of fishes related to the condition of marine waters is one way of good management efforts. Several oceanographic parameters that can affect the distribution of fishes are SST (Sea Surface Temperature), chlorophyll a, salinity, and others. Each type of fish has different optimal level of particular oceanographic parameters. The distribution of oceanographic parameters are effected by West monsoon, East monsoon and the season inbetween. Therefore, by studying oceanographic parameters on a regular basis, we can determine the fishing areas.
