primer yang dinilai adalah mortalitas rumah sakit. Luaran yang dinilai sekunder yang dinilai adalah perbaikan hemodinamik, dan marka apoptosis dan kemampuan prediksi beklin-1, kaspase-3, interleukin-6 dan laktat jam ke-0 terhadap kematian. Analisis regresi cox dilakukan untuk menilai kesintasan pasien di RS dengan prinsip *intention-to treat*. Sebanyak 60 pasien pasca henti jantung karena SKA, 30 di kelompok perlakuan dan 30 di kelompok kontrol diikutsertakan dalam penelitian ini. Mortalitas pada kelompok perlakuan adalah 18 (60%) pasien, sedangkan pada kelompok kontrol adalah 17 (56,67%) pasien. ( $p=0,793$ ; hazard ratio 1,29; [IK] 95% 0,66–2,52). Tidak terdapat perbedaan kadar IL-6, BLE, beclin-1, caspase-3, curah jantung (CJ), VTI, TAPSE, fraksi ejeksi (FE), a-vO<sub>2</sub> diff, dan ScvO<sub>2</sub> di jam ke-6 pasca SSK antara dua kelompok. Laktat, IL-6, dan beclin-1, caspase-3 dapat memprediksi mortalitas pasien pasca henti jantung karena SKA, sedangkan Beklin-1 tidak dapat memprediksi kematian.

**Simpulan:** Pemasangan PBIAD ini tidak memperbaiki mortalitas pasien SKA pasca henti jantung. Laktat, IL-6, dan kaspase-3 dapat memprediksi mortalitas pasien pasca henti jantung karena SKA.

The need for mechanical circulatory support to improve organ perfusion may be considered in the management of post cardiac arrest syndrome patients. Intra-Aortic Balloon Pump (IABP) is the most available and convenient used mechanical circulation aid especially in developing countries such as Indonesia. This study aimed to find out whether early insertion of IABP can reduce in-hospital mortality, length of stay and death markers of cardiac arrest complicating acute myocardial infarction. A randomized trial conducted in National Cardiovascular Center Harapan Kita (NCCHK) Hospital from October 2017–December 2018. Inclusion criteria were all post cardiac arrest due to acute coronary syndrome (ACS) patients aged 18–75 years. Exclusion criteria were history of stroke, anisocoric pupil, previous IABP use, aortic regurgitation, brugada syndrome, and congenital long QT syndrome. The intervention group was given IABP inserted as early as possible in the first 3 hours after spontaneous circulation returned. Patients were randomized into two groups, intervention and controls. Assessment of interleukin-6, lactate clearance, beclin-1, caspase-3, cardiac output, VTI, TAPSE, ejection fraction (EF), a-vO<sub>2</sub> Diff, and ScvO<sub>2</sub> was done in first hour and 6 hours

after return of spontaneous circulation (ROSC). Primary outcome was in-hospital mortality. Secondary outcome was improved hemodynamics, apoptotic markers, and predictive ability of beclin-1, caspase-3, IL-6 and lactate in first hour after ROSC to mortality. Cox regression analysis was performed to assess in-hospital survival with the intention-to-treat principle.

A total of 60 post cardiac arrest due to ACS patients, 30 in intervention group and 30 controls included in this study. In hospital mortality of intervention group vs control was 18 (60%) vs. 17 (56.67%) respectively.  $p = 0.793$ ; hazard ratio 1.29; [95% CI 0.66–2.52]. There's no difference in IL-6, lactate clearance, beclin-1, caspase-3, cardiac output, VTI, TAPSE, ejection fraction (EF), a-vO<sub>2</sub> Diff, and ScvO<sub>2</sub> in 6 hours after ROSC between two groups. Lactate, IL-6, and caspase-3 predicts mortality of post cardiac arrest due to ACS patients while beclin-1 does not.

**Conclusion:** Early insertion of IABP is not improve mortality outcome of post cardiac arrest complicating acute myocardial infarction patients. Lactate, IL-6, and caspase-3 predicts mortality of post cardiac arrest due to ACS patients.
