## Abstrak

Sintesis terhadap CuO, Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>, dan CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> telah berhasil dilakukan dengan menggunakan ekstrak daun jotang kecil (EDJK) dalam sistem dua fasa. Sistem dua fasa berarti sintesis dilakukan pada dua fasa yang berbeda yaitu fase nonpolar (EDJK) dan fase polar (Prekursor). Adanya kandungan metabolit sekunder seperti Alkaloid, saponin, dan steroid dalam EDJK memiliki peranan penting dalam sintesis material. Alkaloid dalam EDJK ini berfungsi sebagai sumber basa lemah dan saponin dan steroid berfungsi sebagai capping agent. Nilai bandgap komposit CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> yang telah berhasil disintesis kemudian adalah sebesar 1.78 eV yang diukur dengan menggunakan UV-Vis DRS. Kinerja Fotokatalitik dari komposit CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> diuji pada fotodegradasi senyawa zat warna malasit hijau (MG) dalam sinar tampak selama 90 menit, dan dibandingkan dengan CuO dan Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. Komposit CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> menunjukkan hasil persen degradasi yang paling tinggi yaitu sebesar 75.95% dibandingkan dengan CuO sebesar 66.73% dan Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> sebesar 46.73%.

.....CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> has been prepared by a two-phase system, consisting of polar precursor solution and non-polar hexane fraction of *Acmella uliginosa* leaf extract (AUE). The secondary metabolites in AUE have an important role in the synthesis of CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. In specific, alkaloid acts as the source of a weak base to produce hydroxide ions in the synthesis of the metal oxide. Meanwhile, saponin and terpenoid are used as the capping agent, to stabilize the particle formation of CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. The optical bandgap value for CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> measured by UV-Vis DRS significantly decreased from 3.68 to 1.78 eV compared to Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. The photocatalytic activity of CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> was investigated degradation of malachite green (MG) under visible light illumination. As a result, CuO-Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> showed the MG degradation percentage of 75.40% after 90 min of illumination time, which is 1.7 times higher than the MG degradation percentage over Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub>. This improved photocatalytic activity is ascribed to the narrower optical bandgap Gd<sub>2</sub>Ti<sub>2</sub>O<sub>7</sub> after decorated by CuO, which can effectively work in the visible region. This research suggests a novel method to prepare alternative photocatalyst for the degradation of malachite green under visible light illumination.
